Additional Catalogues for Engine Parts

Mono-metallic valves:

are produced efficiently in a warm-extruded processor in an upsetting process.

Bi-metallic valves:

make it possible to use the ideal combination of materials both for the shaft and the head.

Function

Valves are precision engine parts and they have to perform four important tasks in the operation of the

Engine:

- Blocking flow areas
- Controlling gas exchange
- Sealing the cylinders to the outside
- Dissipating the heat absorbed by the exhaust gases from combustion to the valve seat ring and to the valve guide.

At temperatures of up to 800° C, each valve opens and closes up to 70 times per second and during the life of the engine it is subjected to an average of 300 million changes of load.

A distinction is generally made between intake valves and exhaust valves.

Intake valves

The valves - which are cooled by the circulation of unburnt gases - have to withstand high mechanical loads, especially upon contact with the valve seat.

Exhaust valves

In addition to the great mechanical demands made on them, exhaust valves are subjected to high thermal stresses and chemical corrosion. Therefore, other materials and more complex production
